# 1.1 Atomic Structure

## Details of the three sub-atomic (fundamental) particles

Particle	Position	Relative Mass	Relative Charge
proton	nucleus	1	+1
neutron	nucleus	1	0
electron	orbitals	1/1840	-1

There are various models for atomic structure

An atom of Lithium (Li) can be represented as follows:

Mass number → 7 Li ← Atomic symbol
Atomic number → 3

The **atomic number**, Z, is the number of protons in the nucleus.

The **mass number**, A, is the total number of protons and neutrons in the atom.

### Number of neutrons = A - Z

### **Isotopes**

Isotopes are atoms with the same number of protons, but different numbers of neutrons.

Isotopes have similar chemical properties because they have the same electronic structure. They may have slightly varying physical properties because they have different masses.

## The time of flight mass spectrometer

The mass spectrometer can be used to determine all the isotopes present in a sample of an element and to therefore identify elements.

It needs to be under a vacuum otherwise air particles would ionise and register on the detector

The following are the essential 4 steps in a mass spectrometer.

### 1. Ionisation

The sample can be ionised in a number of ways. Two of these techniques are electron impact and electrospray ionisation

Learn all these steps carefully!

#### **Electron impact**

- •A vaporised sample is injected at low pressure
- •An electron gun fires high energy electrons at the sample
- •This knocks out an outer electron
- •Forming **positive** ions with different charges e.g. Ti (g)→ Ti<sup>+</sup> (g)+ e<sup>-</sup>

#### **Electro spray Ionisation**

- The sample is **dissolved** in a volatile, polar **solvent**
- injected through a fine **needle** giving a fine mist or aerosol
- the tip of needle has high voltage
- at the tip of the needle the sample molecule, M, gains a proton, H<sup>+</sup>, from the solvent forming MH<sup>+</sup>
- M(g) + H<sup>+</sup> → MH<sup>+</sup>(g)
- The solvent evaporates away while the MH<sup>+</sup> ions move towards a negative plate

Electron impact is used for elements and substances with low formula mass. Electron impact can cause larger organic molecules to fragment.

Electro spray ionisation is used preferably for larger organic molecules. The 'softer' conditions of this technique mean fragmentation does not occur.

#### 2. Acceleration

Positive ions are accelerated by an electric field

•To a constant kinetic energy

$$KE = \frac{1}{2} n v^2$$

KE = kinetic energy of particle (J) m = mass of the particle (kg) v = velocity of the particle (ms<sup>-1</sup>)

Rearranged 
$$v = \sqrt{\frac{2KE}{m}}$$

Given that all the particles have the same kinetic energy, the velocity of each particle depends on its mass. Lighter particles have a faster velocity, and heavier particles have a slower velocity.

You do not need to learn these equations but may be asked rearrange them and use them in a calculation.

### 3. Flight Tube

•The positive ions with smaller m/z values will have the same kinetic energy as those with larger m/z and will move faster.

•The heavier particles take longer to move through the drift area.

•The ions are distinguished by different flight times

t = d/v

t = time of flight (s)

d = length of flight tube (m)

 $v = \text{velocity of the particle (m s}^{-1})$ 

Combining the two equations gives you

$$t = d\sqrt{\frac{m}{2KE}}$$

#### 4. Detection

The ions reach the detector and generate a small current, which is fed to a computer for analysis. The current is produced by electrons transferring from the detector to the positive ions. The size of the current is proportional to the abundance of the species

For each isotope the mass spectrometer can measure a m/z (mass/charge ratio) and an abundance

Sometimes two electrons may be removed from a particle forming a 2+ ion. <sup>24</sup>Mg<sup>2+</sup> with a 2+ charge would have a m/z of 12

**Example** A sample of nickel was analysed and one of the isotopes found was  $^{59}$ Ni. The ions were accelerated to have  $1.000 \times 10^{-16}$  J of kinetic energy and travelled through a flight tube that was 0.8000 m long.

How long would one ion of  $^{59}$ Ni<sup>+</sup> take to travel along the flight tube? The Avogadro constant L =  $6.022 \times 10^{23}$  mol<sup>-1</sup>

Mass of one ion of <sup>59</sup>Ni<sup>+</sup> = mass of one mole of <sup>59</sup>Ni<sup>+</sup>

= 59/ 6.022  $\times$  10<sup>23</sup> = 9.797X10<sup>-23</sup> g = 9.797X10<sup>-26</sup> kg

 $t = d\sqrt{\frac{m}{2KE}}$  t= 0.8000 v( 9.797X10<sup>-26</sup>/(2x 1.000 x 10<sup>-16</sup>)) t=1.771X10<sup>-5</sup> s

The Avogadro constant

## **Calculating Relative Atomic Mass**

The relative atomic mass quoted on the periodic table is a weighted average of all the isotopes

If asked to give the species for a peak in a mass spectrum then give **charge** and **mass number** e.g. <sup>24</sup>Mg<sup>+</sup>

R.A.M = 
$$\Sigma$$
 (isotopic mass x % abundance)  
100

Use these equations to work out the R.A.M

For above example of Mg R.A.M =  $[(78.7 \times 24) + (10.13 \times 25) + (11.17 \times 26)] / 100 = 24.3$ 

R.A.M =  $\Sigma$  (isotopic mass x relative abundance) total relative abundance

If relative abundance is used instead of percentage abundance use this equation

**Example:** Calculate the relative atomic mass of tellurium from the following abundance data: 124-Te relative abundance 2; 126-Te relative abundance 4; 128-Te relative abundance 7; 130-Te relative abundance 6

R.A.M = 
$$[(124x2) + (126x4) + (128x7) + (130x6)]$$
  
19  
= 127.8

**Example:** Copper has two isotopes 63-Cu and 65-Cu. The relative atomic mass of copper is 63.5. Calculate the percentage abundances of these two isotopes.

%abundance 63-Cu =72.5%

%abundance 65-Cu = 27.5%

## Mass spectra for Cl<sub>2</sub> and Br<sub>2</sub>

Cl has two isotopes Cl<sup>35</sup> (75%) and Cl<sup>37</sup>(25%)

Br has two isotopes Br<sup>79</sup> (50%) and Br<sup>81</sup>(50%)

These lead to the following spectra caused by the diatomic molecules

The 160 peak has double the abundance of the other two peaks because there is double the probability of 160 Br<sup>79</sup>-Br<sup>81</sup> as can be both Br<sup>79</sup>-Br<sup>81</sup> and Br<sup>81</sup>-Br<sup>79</sup>

Mass spectrometers have been included in planetary space probes so that elements on other planets can be identified. Elements on other planets can have a different composition of isotopes.

### Measuring the $M_r$ of a molecule

If a molecule is put through a mass spectrometer with an **Electron impact ionisation stage** it will often break up and give a series of peaks caused by the fragments. The peak with the largest m/z, however, will be due to the complete molecule and will be equal to the relative molecular mass ,  $M_r$  , of the molecule. This peak is called the parent ion or **molecular ion** 

## Spectra for C<sub>4</sub>H<sub>10</sub>

If a molecule is put through a mass spectrometer with **electro spray ionisation** then fragmentation will not occur. There will be one peak that will equal the **mass of the MH**<sup>+</sup> **ion**. It will therefore be necessary to subtract 1 to get the  $M_r$  of the molecule. So if a peak at 521.1 is for MH<sup>+</sup>, the relative molecular mass of the molecule is 520.1.

### **Electronic Structure**

#### Models of the atom

An early model of the atom was the Bohr model (GCSE model) (2 electrons in first shell, 8 in second etc.) with electrons in spherical orbits. Early models of atomic structure predicted that atoms and ions with noble gas electron arrangements should be stable.

#### The A-level model

Principle level	1	2	3	4
Sub-level	1s	2s, 2p	3s, 3p, 3d	4s, 4p, 4d, 4f

An atom fills up the sub shells in order of increasing energy (note 3d is higher in energy than 4s and so gets filled after the 4s)  $1s \rightarrow 2s \rightarrow 2p \rightarrow 3s \rightarrow 3p \rightarrow 4s \rightarrow 3d \rightarrow 4p \rightarrow 5s \rightarrow 4d \rightarrow 5p$ 

### Writing electronic structure using letters and numbers

For calcium 1s<sup>2</sup> 2s<sup>2</sup> 2p<sup>6</sup> 3s<sup>2</sup> 3p<sup>6</sup> 4s<sup>2</sup>

### Using spin diagrams

## Shapes of orbitals

Orbitals represent the mathematical probabilities of finding an electron at any point within certain spatial distributions around the nucleus.

Each orbital has its own approximate, three dimensional shape.

It is not possible to draw the shape of orbitals precisely.

•s sublevels are spherical

• p sublevels are shaped like dumbbells

The periodic table is split into blocks.

A s block element is one whose outer electron is filling a s-sub shell e.g. sodium 1s<sup>2</sup> 2s<sup>2</sup> 2p<sup>6</sup> 3s<sup>1</sup>

A **p** block element is one whose outer electron is filling a p-sub shell e.g. chlorine 1s<sup>2</sup> 2s<sup>2</sup> 2p<sup>6</sup> 3s<sup>2</sup> 3**p**<sup>5</sup>

A **d** block element is one whose outer electron is filling a d-sub shell e.g. vanadium 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>3</sup>

#### Electronic structure for ions

When a positive ion is formed electrons are lost from the outermost shell.

Mg is  $1s^2 2s^2 2p^6 3s^2$  becomes Mg<sup>2+</sup> is  $1s^2 2s^2 2p^6$ 

When a negative ion is formed electrons are gained O is  $1s^2 2s^2 2p^4$  becomes  $0^{2-}$  is  $1s^2 2s^2 2p^6$ 

### Electronic structure of d-block elements

The electronic structure of the d-block has some complications. As mentioned earlier, conventionally we say that 4s fills before 3d and so we write them in that order. There is, however, disagreement in the scientific community about whether this is true.

If you look at the electronic structures below you will see both chromium and copper have an unusual arrangement in having a half filled 4s sub shell.

You will also see that when d-block elements form ions they lose the 4s electrons first.

You may find if you research different reasons for these observations. It may well be many of the reasons are false and we have to accept that some things in chemistry don't neatly follow patterns we can explain. You do need to learn these electronic structure though!

Sc 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>1</sup> Ti 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>2</sup> V 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>3</sup> Cr 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>1</sup>3d<sup>5</sup> Mn 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>6</sup> Fe 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>6</sup> Co 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>7</sup> Ni 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>8</sup> Cu 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>10</sup> Zn 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup> 4s<sup>2</sup>3d<sup>10</sup>

When forming ions lose 4s before 3d

Cu<sup>2+</sup> [Ar] 4s<sup>0</sup>3d<sup>9</sup>
Zn<sup>2+</sup> [Ar] 4s<sup>0</sup>3d<sup>10</sup>

## **Ionisation Energies**

### **Definition: First ionisation energy**

The first ionisation energy is the enthalpy change when one mole of gaseous atoms forms one mole of gaseous ions with a single positive charge

This is represented by the equation:

### **Definition: Second ionisation energy**

The second ionisation energy is the enthalpy change when one mole of gaseous ions with a single positive charge forms one mole of gaseous ions with a double positive charge

This is represented by the equation:

$$Ti^{+}_{(g)} \rightarrow Ti^{2+}_{(g)} + e^{-}$$

## Factors that affect ionisation energy

There are three main factors

1. The attraction of the nucleus

(The more protons in the nucleus the greater the attraction)

2. The distance of the electrons from the nucleus

(The bigger the atom the further the outer electrons are from the nucleus and the weaker the attraction to the nucleus)

3. Shielding of the attraction of the nucleus

(An electron in an outer shell is repelled by electrons in complete inner shells, weakening the attraction of the nucleus)

Successive ionisation energies

The patterns in successive ionisation energies for an element give us important information about the electronic structure for that element.

### Why are successive ionisation energies always larger?

The second ionisation energy of an element is always bigger than the first ionisation energy. When the first electron is removed a positive ion is formed.

The ion increases the attraction on the remaining electrons and so the energy required to remove the next electron is larger.

#### How are ionisation energies linked to electronic structure?

### **Explanation**

The fifth electron is in a inner shell closer to the nucleus and therefore attracted much more strongly by the nucleus than the fourth electron.

It also does not have any

It also does not have any shielding by inner complete shells of electron

The equation for 1st ionisation energy always follows the same pattern.

It does not matter if the atom does not normally form a +1 ion or is not gaseous

Many questions can be answered by application of these factors

Example: What group is this element in?

	1	2	3	4	5
Ionisation energy kJ mol <sup>-1</sup>	590	1150	4940	6480	8120

Here there is a big jump between the 2nd and 3<sup>rd</sup> ionisations energies which means that this element must be in group 2 of the periodic table as the 3rd electron is removed from an electron shell closer to the nucleus with less shielding and so has a larger ionisation energy

# The first Ionisation energy of the elements

The shape of the graph for periods two and three is similar. A repeating pattern across a period is called **periodicity**.

The pattern in the first ionisation energy gives us useful information about electronic structure

You need to carefully learn the patterns

## Q. Why has helium the largest first ionisation energy?

A. Its first electron is in the first shell closest to the nucleus and has no shielding effects from inner shells. He has a bigger first ionisation energy than H as it has one more proton

### Q. Why do first ionisation energies decrease down a group?

A. As one goes down a group, the outer electrons are found in shells further from the nucleus and are more shielded so the attraction of the nucleus becomes smaller

Many questions can be answered by application of the 3 factors that control ionisation energy

### Q. Why is there a general increase in first ionisation energy across a period?

A. As one goes across a period the electrons are being added to the same shell which has the same distance from the nucleus and same shielding effect. The number of protons increases, however, making the effective attraction of the nucleus greater.

### Q. Why has Na a much lower first ionisation energy than neon?

This is because Na will have its outer electron in a 3s shell further from the nucleus and is more shielded. So Na's outer electron is easier to remove and has a lower ionisation energy.

#### Q. Why is there a small drop from Mg to Al?

Al is starting to fill a 3p sub shell, whereas Mg has its outer electrons in the 3s sub shell. The electrons in the 3p subshell are slightly easier to remove because the 3p electrons are higher in energy and are also slightly shielded by the 3s electrons

### Q. Why is there a small drop from P to S?

With sulfur there are 4 electrons in the 3p sub shell and the 4th is starting to doubly fill the first 3p orbital.

When the second electron is added to a **3p orbital** there is a slight **repulsion** between the two negatively charged electrons which makes the second electron easier to remove.

phosphorus 1s<sup>2</sup> 2s<sup>2</sup> 2p<sup>6</sup>3s<sup>2</sup>3p<sup>3</sup>

sulfur 1s2 2s2 2p63s23p4

N Goalby chemrevise.org

Learn carefully the explanations for these two small drops as they are different to the usual factors

### Patterns in the second ionisation energy.

If the graph of second ionisation or each successive element is plotted then a similar pattern to the first ionisation energy is observed but all the elements will have shifted one to the left.

The group 1 elements are now at the peaks of the graph

Lithium would now have the second largest ionisation of all elements as its second electron would be removed from the first 1s shell closest to the nucleus and has no shielding effects from inner shells. Li has a bigger second ionisation energy than He as it has more protons.
